Abstract

Purpose: The aim of this study is to assess the impact of Polycystic Ovary Syndrome (PCOS) on Bulgarian patients' QoL through a Polycystic Ovary Syndrome Questionnaire (PCOSQ).

Methods: A pilot survey was conducted in a sample of individuals aged 15 to 35 (n=24) from Sofia, Bulgaria. Data were collected *via* PCOSQ. The PCOSQ scale was translated into Bulgarian and standardized by forward translation, backward translation, and a pre-test.

Results: The mean age of the sample was 25.6 ± 6.4 (range 15-35). Results from the study found that women with PCOS had a lower appraisal of their appearance because of their weight. The lowest and the highest results were obtained for their mental and emotional status (q.18-1.92 and q.7-4.42). As a factor group-the lowest results were obtained for the questions concerning their overweight-all the 5 questions were in the range of 3.25-3.58. The highest result (-4.42) was reported for in factor group "emotions".

Conclusion: This pilot study found that the mean level of QoL is 3.7 on a scale of 1 to 7. The main problematic question associated with the disease is women's overweight. The large variance in the levels of emotions of study subjects shows the need to explore this issue further in a larger cohort of patients. It can be concluded that the management of PCOS is urgently needed and the psychological health of these patients must be monitored regularly.

Keywords: PCOS, PCOSQ, QoL, Bulgaria.

Introduction

Polycystic ovary syndrome was first described by Stein et al. in 1935 and according to them; the symptoms included amenorrhoea and hirsutism in obese women suffering from infertility [1]. Polycystic ovarian syndrome (PCOS) is one of the most widespread endocrine disorders in women of the reproductive age of 12-45 y [2,3]. It is a common disorder of chronically abnormal ovarian function and hyperandrogenism. According to the National Institutes of Health in 1990, there are three main characteristics of PCOS: oligomenorrhoea, hyperandrogenism, and the absence of other endocrine disorders [4]. The presence of polycystic ovaries, as shown by ultrasonography, was not included in the definition but this feature is mandatory. Patients with PCOS complain of infertility, menstrual disturbance, or hirsutism, with or without acne.

At present, there are two main definitions for PCOS, which are also the topic of intense debate. The 1990 National Institutes of Health (NIH) criteria require the presence of chronic anovulation plus clinical or biochemical signs of hyperandrogenism, whereas the 2003 Rotterdam criteria require the presence of two or more of the following: chronic

anovulation, clinical or biochemical signs of hyperandrogenism, and polycystic ovaries [5].

Fortunately, in 2003 at a joint consensus meeting between the American Society of Reproductive Medicine and the European Society of Human Reproduction and Embryology, a unifying definition of the PCOS was proposed, encompassing a description of the morphology of the polycystic ovary, ovulatory disorder and hyperandrogenism. The prevalence of polycystic ovary syndrome, as defined by the 1990 National Institutes of Health (NIH) criteria, in unselected populations of women of reproductive age is between 6.5% and 8% [6]. According to another survey, it affects 5%-10% of women of reproductive age [7]. In general worldwide, PCOS affects up to 6%-10% of this population [8].

The prevalence of PCOS varies depending on which criteria are used to make the diagnosis, but is as high as 15%-20% when the European Society for Human Reproduction and Embryology/American Society for Reproductive Medicine criteria are used [9]. The prevalence of PCOS has been determined among women in different countries but with different findings. A study conducted in China demonstrated a 2.2% prevalence of PCOS, while a study conducted in Mexico reported a 6% prevalence of PCOS among women of

reproductive age according to National Institute of Health criteria [10,11]. In addition, a prospective study conducted in unselected Caucasian women from Spain recorded a 6.3% prevalence of PCOS [12].

PCOS is one of the most common endocrine disorders in women of reproductive age that has substantial psychological, social, and economic consequences. Decreased quality of life characterized by symptoms of depression, decreased sexual satisfaction, and problems with female self-esteem and self-image have been reported [13,14]. There are many questionnaires for measuring quality of life (QoL), but the one specifically designed to measure the range of health-related problems experienced by women with PCOS is a health-related quality of life questionnaire (PCOSQ) for women with PCOS [15]. It examines disease-related decreases in QoL in PCOS women.

After performing a detailed document survey on the effects of PCOS on Eastern European women, and particularly Bulgarian women, we did not observe any consistent findings. Therefore, the aim of this study is to assess the impact of PCOS on Bulgarian patients' QoL through PCOSQ.

Methods

A pilot survey was conducted in a sample of individuals aged 15 to 35 (n=24) from Sofia, Bulgaria who were diagnosed with PCOS. They were diagnosed according to the European Society of Human Reproduction and Embryology/American Society for Reproductive Medicine criteria. Patients were recruited from pharmacies in Sofia, based on referrals from pharmacists and their disease dossiers. All recruited women were required to be otherwise healthy. Women were excluded from the study if they had another major illness that substantially influenced their quality of life or another cause of androgen excess, e.g. congenital adrenal hyperplasia. The Ethics Committee of the Medical University of Sofia approved the study protocol. All participants provided written informed consent before entering the study, and all questionnaires were made anonymous before evaluation.

Data were collected *via* the Polycystic Ovary Syndrome Questionnaire (PCOSQ). The PCOSQ scale was translated into Bulgarian and standardized by forward translation, backward translation, and a pre-test. (WHO Process of translation and adaptation of instruments, [16]). The PCOSQ consists of five domains, each relating to a particular symptom of PCOS, including body hair, emotions, overweight, menstrual problems and infertility. Each question on the PCOSQ is associated with a 7-point scale in which 7 represents optimal function and 1 the poorest function.

The data were processed using the statistical package SPSS 20.0.

Results

Of the 24 women who agreed to take part in the study, 24 returned questionnaires (100%). The mean age of the sample

was 25.6 ± 6.4 (range 15-35). The mean duration of the disease is 39.8 ± 30.2 months (range 6-96). The mean BMI is 29.8 ± 4.8 and 16.7% (n=4) were clinically obese (BMI ≥ 30) (Table 1).

Table 1. Socio-demographic characteristics in women with PCOS.

Characteristics	n=24
Age	25.6 ± 6.4
Duration of disease (months)	39.8 ± 30.2
BMI	29.8 ± 4.8

The 26 questions of PCOSQ were grouped into 5 main domain topics: body hair, emotions, overweight, menstrual problems and infertility and were assessed by a 7-point scale (1-poor/7-no problem). Results from the study found that women with PCOS had more negative assessment of their appearance because of their weight. High levels of anxiety and depression due to worrying and self-consciousness due to their disease were reflected in a lower PCOSQ score. The lowest and highest results were obtained for questions concerning their emotional status (q.18-1.92 and q.7-4.42). As a factor group, the lowest results were obtained for the questions concerning their overweight; all the five questions are in the range 3.25-3.58. The highest result (4.42) was documented for the factor group of emotions (Table 2).

Table 2. Survey results-impact score of every question.

Factor	Question no.	Impact score
Body hair	1	3.33
	9	4.08
	15	3.83
	26	3.75
Emotions	2	3.67
	4	3.91
	6	4.25
	7	4.42
	11	3.5
	14	3.92
	16	4.08
	17	2.92
Overweight	18	1.92
	23	3.92
	3	3.33
	10	3.58
	12	3.25
	22	3.42

	24	3.5
	8	3.42
Menstrual problems	19	4.25
	20	4.17
	21	3.91
	5	4.08
Infertility	13	3.67
	25	3.5

The impact score of every factor shows that all the 5 factors are in the same range-between 3.42 and 3.94. The lowest score was for emotional status of the patients, while the highest was reflected in their concern about menstrual disturbances due to PCOS (Table 3). Patients with PCOS reported good quality of life (QoL) "a good bit of the time" and "some of the time".

Table 3. Survey results-impact score of every factor.

Factor	Mean impact score
Body hair	3.75
Emotions	3.65
Overweight	3.42
Menstrual problems	3.94
Infertility	3.75

Discussion

The mean factor scores for the PCOSQ reflect the negative impact PCOS can have upon the quality of life of women with this disease. Weight and emotions appeared to be the most significant aspects of the illness according to this cohort. These results confirm the picture that shows previous studies in the region [3,17,18]. The finding that weight caused the most negative impact on quality of life has implications for the management of the condition; furthermore, some studies have shown that 50% of women with PCOS suffer from obesity or are overweight, and it was concluded that the best method to manage this problem remains unclear [19].

Quality of life is increasingly becoming an outcome measure in the long-term management of chronic conditions that demand coping strategies. This is due to the fact that the clinical results do not assess the physical, emotional and social effects' of the disease on those living with the condition. The social predicaments and developmental tasks that all adolescents face may mediate a patient's ability to cope with PCOS [20].

The small size of the respondents was a limitation of this study. Nonetheless, it serves to highlight some important trends. Future studies are needed to compare patients from different areas of Bulgaria and to assess the effects of standard of living on the QoL of these patients as Sofia is the capital of Bulgaria and has the highest cost-of-living allowance.

Conclusion

PCOSQ is a good tool for measuring the QoL of women with PCOS in Bulgaria. The findings of this pilot study indicate that the mean level of QoL in Bulgaria is 3.7% for women with PCOS. The main problematic question and topic associated with the disease is women's overweight. The large variance in the levels of emotions shows the need to explore this issue further in a larger cohort of patients. But overall, it can be concluded that better understanding for the management of PCOS is urgently needed and the psychological health of these patients must be monitored and attended to regularly.
