Abstract

Background: The prevalence of ESRD has risen rapidly worldwide due to congenital anomalies of the kidney and urinary tract (CAKUT). In the developing countries, these abnormalities could be delay in diagnosed, and treatment. The aim of this study was to analyzed renal survival patients of CAKUT and outcomes in chronic kidney disease.

Methods: In this cohort study, 53 CAKUT patients were followed up. Clinical end points were censored on 31st September, 2017. ESRD or death was assigned as a dependent variable. Renal survival was measured from the date of patient chronological ages to the date of initiation of renal dialysis or to the date of first eGFR <15 ml/min per 1.73 m² (stage 5) or death secondary to renal causes.

Results: The frequency of renal diagnosis based on CAKUT abnormalities are 38 in obstructive type and 15 in non obstructive type. Mean age for obstructive type was 8.9 ± 4.42 years and for non obstructive type 9.92 ± 2.42 years. Mean basal glomerular filtration rate was 52.8 ml/min/1.73 m² for obstructive type and 55.4 ml/min/1.73 m² for non obstructive type. Median follow-up of all CAKUT patients was 15 years (14.54-15.46 years). The median renal survival for obstructive type was 14.50 (8.09-20.90) years and for non-obstructive type 15.00 (6.92-23.07). There was no significant difference them.

Conclusion: The understanding management of CAKUT makes it possible for children with CAKUT to have fewer complications, have longer renal survival, and survive even with ESRD through renal replacement therapy.

Introduction

The prevalence of ESRD has risen rapidly in worldwide due to congenital anomalies of the kidney and urinary tract (CAKUT). These anomalies are the spectrum of malformations that occur in the kidney, ureter, bladder and urethra [1] result from defective development of the kidney and the urinary tract. Most CAKUT cases in developing countries lack of pre natal screening, delay treatment and progression to end stage renal disease (ESRD), it accounts for 34-59% of pediatric population and has important impact on renal survival. Renal survival in pediatric population markedly varies depending on the cause of renal diseases, such as CAKUT are more common in infant, toddler and school-age children [2].

Depending on their types and severity, children with CAKUT often have varying degrees of a reduced number of nephrons at birth. Renal scarring can further increase the risk of decline glomerular filtration rate (GFR) in children. Once the loss of nephrons and functional renal mass reaches a certain point, the remaining nephrons begin irreversible sclerosis process that lead to ESRD. Apparently, tubuloglomerular feedback mechanisms are disturbed in patient with ESRD [3]. Hypertension and proteinuria may develop in children with CAKUT and further aggravate renal function unless they are treated. We hypothesized that many patients with CAKUT manifest ESRD and determined rates progression between obstructive and non-obstructive type of CAKUT.

Materials and Methods

Data Source

Patients

The records of 53 children patients diagnosed with CAKUT were included in the analysis of this retrospective cohort...
Renal survival analysis of CAKUT and outcomes in chronic kidney disease.

study. Inclusion criteria were children who were admitted to the H. Adam Malik Hospital from 2007 to 2017 with CKD (stages 2-4) and had at least 1 year of follow-up.

Renal Survival Analysis

Renal survival time, defined as the time from onset of the cause to confirmed ESRD, was calculated from the index date to the first date of confirmed ESRD diagnosis. Renal survival time indicated the duration of an enrolled patient with ESRD who had preserved renal function independent of renal replacement therapy. Because of CAKUT is lifelong disease so chronologic age was used as the index date instead. To ensure the validity of the index date, the patients were followed-up for at least 1 year and those with incomplete observation were not included in this study.

ESRD was defined as eGFR <15 ml/min per 1.73 m² or requiring renal replacement therapy for 3 months. eGFR was calculated using the formula of Schwartz [4]. Renal function was graded according to the Kidney Diseases Outcomes Quality Initiative guidelines: stage 1, ≥ 90 ml/min per 1.73 m²; stage 2, 60-89 ml/min/1.73 m²; stage 3, 30-59 ml/min/1.73 m²; stage 4, 15-29 ml/min/1.73 m² and stage 5, <15 ml/min/1.73 m² [5].

Initial treatment was defined as the first treatment modality for ESRD after the onset date. Modalities such as peritoneal dialysis, hemodialysis, were identified by hospitalization and outpatient databases within 3 months after the onset of ESRD. If multiple modalities were given, the initial treatment modality was considered in the order of peritoneal dialysis, and hemodialysis. Patients without a complete record of treatment modalities were not included.

Outcome

Clinical end points were censored on 31st September, 2017. ESRD or death was assigned as a dependent variable. Renal survival was measured from the date of patient chronological ages to the date of initiation of renal dialysis or to the date of first eGFR <15 ml/min/1.73 m² (Stage 5) or death secondary to renal causes.

Statistical Analysis

The data are presented as mean ± SD or median (interquartile range) or percentage as appropriate. Kaplan-Meier survival analysis was used to estimate patient and renal survival and the log rank test was used to compare the difference between the survival curves. Univariate and multivariate analyses of survival were performed by Cox regression. The results were expressed as hazard ratios (HRs) with 95% confidence intervals (95% CIs).

Ethical Aspects

The Ethics Committee of Medicine Faculty University of Sumatera Utara approved the study and the parents for children gave written informed consent to participate in this study.

Results

The frequency of renal diagnosis based on CAKUT abnormalities are described in Table 1. Pelvic uretero junction obstruction (PUJO) was the higher frequency in obstructive type and reflux in non-obstructive type.

The clinical characteristic of the study participants are described in Table 2. Mean age for obstructive type was 8.9 ± 4.42 years and for non obstructive type 9.92 ± 2.42 years. Mean basal glomerular filtration rate was 52.8 ml/min/1.73 m² for obstructive type and 55.4 ml/min/1.73 m² for non obstructive type.

Median follow-up of all CAKUT patients was 15 years (14.54-15.46 years), that means 50% of subject were died in time 15 year (Table 3 and Figure 1).

**Discussion**

CAKUT was the most prevalent primary renal disease that caused to ESRD in pediatric population. They represent a highly heterogeneous group, with a few being incompatible with life while minor abnormalities can be asymptomatic for long periods of time. In CAKUT pediatric population with stage 2 and or stage 3 CKD, had a high incidence of ESRD over 5 years. Anomalies of the kidney are more common than those of the lower urinary tract and often lead to ESRD [6]. CAKUT patients have unique survival renal analysis so to address this hypothesis; we compared rates of progression and outcomes in a subgroup of patients with CAKUT as obstructive and non obstructive. Our data demonstrate that non obstructive CAKUT do not have better survival rates compared to patients with obstructive
The prognosis in CAKUT depends on initial therapy, compliance to therapy, renal function before and after correction of the obstruction, age at diagnosis, the presence of VUR at the time of diagnosis, accompanying prevention and treating of UTI or Catheter-Associated Urinary Tract Infection (CAUTI), proteinuria and hypertension [14]. All of these factors are helpful to predict the progression of the disease and determine a long-term prognosis [15,16]. The understanding management of CAKUT make it possible for children with CAKUT to have fewer complications, have longer renal survival and survive even with ESRD through renal replacement therapy.

Conclusion

The understanding management of CAKUT makes it possible for children with CAKUT to have fewer complications, have longer renal survival, and survive even with ESRD through renal replacement therapy.
