Abstract

In this study the effect of Centella asiatica L. extract was studied against genotoxic doses of ethinylestradiol on human lymphocytes culture. The different doses of C. asiatica L. extract i.e. 1.075x10^-4, 2.125x10^-4 and 3.15x10^-4 g/ml were treated separately with 5 µM of ethinylestradiol. Similar treatments were given with 10 µM of ethinylestradiol. The treatments result in a significant dose dependent decrease in chromosomal aberrations and sister chromatid exchanges on human lymphocyte cultures induced by 5 and 10 µM of ethinylestradiol. The selected doses of C. asiatica L. extract were not genotoxic itself. Hence it is concluded that C. asiatica L. extract reduced the genotoxic damage during the ethinylestradiol therapy in patients and thereby reducing the chances of cancer development in humans.

Key words: Centella asiatica L, chromosomal aberrations, human lymphocytes, natural products, sister chromatid exchanges

Accepted March 07 2009

Introduction

Centella asiatica L. belongs to the family Umbellifera. It is known as Mandukparni or Indian Penny Wort. It is found in swampy areas of India, commonly as a weed in crop fields and in other waste places throughout India up to an altitude of 600 m [1]. The crude extract of C. asiatica and the products derived from it have various pharmacological properties [2-6]. The crude extract of C. asiatica was shown to be non-toxic in normal human lymphocytes [7], and reduced the genotoxic effects of methyl methanesulphonate and cyclophosphamide in cultured human lymphocytes [8].

Conjugated estrogens, have been listed in the fourth annual report on carcinogenesis (ROC), as human carcinogens [9]. A number of individual steroidal estrogens including estradiol-17β and mestranol were listed in the ROC as reasonably anticipated human carcinogens [9]. Steroidal estrogens are placed in a Group I as carcinogenic to humans, on the basis of sufficient evidence of carcinogenicity in humans [10]. Ethinylestradiol is used with various progestogens, in combined oral contraceptive formulations [11]. There are sufficient evidences for the carcinogenicity of ethinylestradiol in experimental animals [12]. It has also been reported to cause aneuploidy in Chinese Hamster DON Cells in vitro [13], aneuploidy and polyplody both, in V79 cells in vitro [14]. Estrogens are used in the treatment of sexual and metabolic disorders and also in oral contraceptives [15]. Prolonged use of estrogens has been reported to develop various types of malignancies in human and experimental animals [15]. The genotoxic effects of estrogens/ progestins can be reduced by the use of antioxidants [16-22] and natural plant products [23-28]. The genotoxicity testing provides human a risk assessment. An increase in frequency of chromosomal aberrations in peripheral blood lymphocytes is associated with an increased overall risk of cancer [29,30].

Any reduction in the genotoxicity gives an indication of the lesser possibility of carcinogenesis [31]. The majority of populations use traditionally natural preparations derived from the plant material for the treatment of various diseases, and for that reason it becomes necessary to assess the mutagenic potential or modulating action of plant extract in combination with other substances. In an earlier study, ethinylestradiol was found to be genotoxic at five and 10 µM [32]. Herbal preparations can be useful in taking care of the genotoxic effects of certain drugs. The aim of this work is to study the effect of C. asiatica L. extract against the genotoxic doses of ethinylestradiol.
Effect of Centella asiatica L.

Material and Methods

Chemicals
Ethinylestradiol (CAS No.: 57-63-6, Sigma); RPMI 1640, Fetal calf serum, Phytohaemagglutinin-M, Antibiotic-antimycotic mixture (Gibco); Dimethyl sulphoxide, 5-Bromo-2-deoxy uridine; Colchicine (SRL, India), Giemsa stain (Merk).

Extract preparation
C. asiatica L. leaves were collected from the nursery of Forest Research Institute (FRI), Dehradun (UA) and were air dried and ground to fine powder. Extraction was performed by soaking samples (30 g of dry weight) in 300 ml of acetone for 8-10 h at 40-60°C in Soxhlet's apparatus. After filtration, the excess of solvent was removed by rotary evaporator. The extract concentrations of 1.075x10^-4, 2.125x10^-4 and 3.15x10^-4 g/ml of culture medium were established [8].

Human lymphocyte culture
Duplicate peripheral blood cultures were prepared according to Carballo et al. [33]. Briefly, heparinized blood samples (0.5 ml), were obtained from healthy female donors and were placed in a sterile culture bottles containing seven ml of RPMI-1640 medium, supplemented with fetal calf serum (1.5 ml), antibiotic-antimycotic mixture (1.0 ml) and phytohaemagglutinin (0.1 ml). The culture bottles were kept in an incubator at 37°C for 24 hours.

Chromosomal aberration analysis
After 24 hours, 5 µM of ethinylestradiol treatment (dissolved in dimethylsulphoxide, 5 µl/ml) was given separately with 1.075x10^-4, 2.125x10^-4 and 3.15x10^-4 g/ml of Centella asiatica L. extract. Similarly, 10 µM of ethinylestradiol was also given with the same three doses of C. asiatica extract. About, 0.5 ml of S9 mix (supplemented with NADP) was also given along with the treatments for 6 h. The cultures were washed with fresh RPMI 1640 and kept for another 48 hours in an incubator. Mitotic arrest was performed by adding 0.2 ml of colchicine (0.2 µg/ml). Hypotonic treatment and fixation were performed in the same way as described for the chromosomal aberration analysis. The sister chromatid exchange average was taken from an analysis of 50 metaphases during second cycle of division [35].

Statistical analysis
Student ‘t’-test was used for analysis of CAAs and SCEs. Regression analysis was performed using Statistica Soft Inc.

Results
Ethinylestradiol induced a significant increase of abnormal metaphases as compared to the untreated at 5 and 10 µM. A significant dose dependent decrease in number of abnormal metaphase was observed when 5 and 10 µM of ethinylestradiol was treated separately, with the different doses of C. asiatica extract, i.e. 1.075x10^-4, 2.125x10^-4 and 3.15x10^-4 g/ml (Table 1). For a number of abnormal metaphases and sister chromatid exchanges, a decrease in slope of linear regression lines with increase in dose of the extract was observed in each treatment. For abnormal metaphases the treatment of 5 µM (F = 29.14; P less than 0.04) and 10 µM (F is equal to 12.65; P < 0.05) of ethinylestradiol, with the increase in the doses of C. asiatica extract results in the decrease in the slope of the linear regression lines (Figures 1 and 2).
For sister chromatid exchange analysis, the treatment of 5 µM (F = 35.19; P < 0.01) and 10 µM (F = 19.69; P < 0.03) of ethinylestradiol, with the increase in the dosages of C. asiatica extract, the decrease in slope of linear regression lines was observed (Figure 3 and 4).

**Discussion**

The results of the study reveal that the selected dosages of the plant extract were not genotoxic *per se*, but reduced the genotoxic damage of ethinylestradiol on human lymphocytes *in vitro*. In our earlier study, three doses of ethinylestradiol (1, 5 and 10 µM) were studied [32]. Ethinylestradiol was found to be genotoxic at five and 10 µM only in the presence of S9 mix supplemented with NADP. International Agency on Cancer (IARC), mainly on the basis of epidemiological studies classifies steroidal estrogens and estrogen progestins combinations among agents carcinogenic to humans (Group 1), progestins as possibly carcinogenic (Group 2) and androgenic anabolic steroids, as probably carcinogenic (Group 2A) [36]. Cancer is characterized by genetic instability, i.e. gross chromosomal abnormalities, which consist of translocation and gene amplifications. Molecular and cytogenetic evidence indicates that the induction of structural and numerical chromosome aberrations in cell play an important role in the neoplastic development of certain tumors [37]. An increase in frequency of chromosomal...
Effect of Centella asiatica L.

aberrations in peripheral blood lymphocytes is associated with an increased overall risk of cancer [29,30]. Genetic toxicology tests are in vitro and in vivo assays designed to detect compounds that induce genetic damage directly or indirectly.

Any kind of chromosomal damage may play an important role in many malignancies. The ready quantifiable nature of sister chromatid exchanges with high sensitivity for revealing toxicant-DNA interaction and the demonstrated ability of genotoxic chemicals to induce significant increase in sister chromatid exchanges in cultured cells has resulted this endpoint being used as indicator of DNA damage in blood lymphocytes of individual exposed to genotoxic carcinogens [31]. The above genotoxic endpoints are well known markers of genotoxicity and any reduction in the frequency of these genotoxic endpoints gives us an indication of the anti-genotoxicity of a particular compound [31].

At present much attention of preventive medicine research is focused on natural antioxidants, leading to isolation and identification of new biologically active molecules by the pharmaceutical industry. The crude extract of plants may...
contribute to total intake of plant antioxidants and be even better source of dietary antioxidants [38].

The compounds present in the extract may inhibit the promutagen bioactivation by blocking the oxidation processes or react with electrophilic metabolites of promutagens [39]. The verification of the possible mutagenic and/or anti-mutagenic effects of medicinal plants infusion/extracts is another important factor in studies. Such effects have been elucidated in some plant species by using various test systems [40]. Medicinal herbs contain complex mixtures of thousand of compounds that can exert their antioxidant and free radical scavenging effect either separately or in synergistic ways [41]. Many plant products protect against xenobiotics either by inducing defoxifying enzymes or by inhibiting oxidative enzymes [42]. Detoxification systems play a major role in preventing carcinogenesis, but also an important role in preventing xenobiotic as well as indogenous toxicity. Phytochemicals plays an important role in inhibition of carcinogenesis [43]. Some plant extract may possess substances that can modulate the genotoxicity of other compounds.

The data obtained in this study suggests that the compounds present in the extract of *C. asiatica* are not mutagenic on their own or when associated with ethinylestradiol in the presence of NADP.

The protective effect observed in the present study i.e. significant reduction in the frequency of cells with chromosomal damage and sister chromatid exchanges may be due to the direct action of the compounds present in the extract on ethinylestradiol by inactivating it enzymatically or chemically. The genotoxic effects of ethinylestradiol have been attributed to the bio-activation of ethinylestradiol in the presence of S9 mix supplemented with NADP [32]. The compounds present in the extract may also enhance the DNA repair system or DNA synthesis or even may prevent the bioactivation of certain chemicals [44]. Our earlier reports on synthetic progestins showed that they are genotoxic in *in vitro* [45-48] and *in vivo* [49,50]. A reduction in the frequency of SCE and chromosomal aberrations in the test system thereby indicates the possibility of reducing the chances of carcinogenesis during the ethinylestradiol therapy in patients.

**Conclusion**

The extract of *Centella asiatica* *L.* is potent enough to reduce the genotoxic damage of ethinylestradiol. The results of the present study suggest that the plant extract can form the basis of herbal medicine as it has antioxidants that are responsible for the reduction of the genotoxic damage of the drugs. The prolonged use of ethinyl estradiol has been reported to induce cancer. Any reduction in the frequency of CAs and SCEs thereby gives an indication of little chances of developing cancer. The extract of *Centella asiatica* reduces the frequency CAs and SCEs induced by ethinyl estradiol.
