Description
We herein demonstrate a case of a new paracentral scotoma following SARS-CoV-2 infection. A 34-year-old male presented with a two-month history of an acute, oval-shaped paracentral scotoma in the right eye which developed in April 2020, four days following a febrile illness with cough. Nasopharyngeal swab testing confirmed a diagnosis of COVID-19. In June 2020, the patient sought an ophthalmic evaluation for a persistent scotoma. At that time, the patient demonstrated normal visual acuities and an unremarkable funduscopic exam (Figure 1a, right eye only). A superotemporal scotoma was detected on formal visual field testing while infrared imaging (Figure 1b) revealed a dark oval lesion inferonasal to the fovea (arrow), correlating with retinal changes seen on optical coherence tomography. Optical coherence tomography demonstrated an area of ellipsoid zone disruption and the collapse of the overlying outer nuclear layer (Figure 1c). Fundus autofluorescent imaging was normal. Fluorescein angiography was deferred. These rather subtle findings are suggestive of a late presentation of acute macular neuroretinopathy secondary to COVID-19.
