Introduction

Ventricular tachycardia (VT) arising from the right ventricular outflow tract (RVOT) is one of the most common types of idiopathic ventricular arrhythmias. RVOT-VTs exhibit the following characteristics [2,3]: they usually occur in patients without overt structural heart disease, (2) the surface 12-lead ECG typically shows left bundle branch block morphology and inferior axis, and (3) the tachycardia typically arises from a discrete area of the myocardium in the RVOT area. Although pathogenic mechanisms in the genesis of RVOT-VT remained largely unknown, activation of sympathetic tone has been shown to play an important role in provoking as well as maintaining these arrhythmias. The frequency of ventricular arrhythmias is often increased during periods of wakefulness and activity, and they frequently disappear entirely during sleep. They are sensitive to catecholamine infusion, and typically terminate in response to betablockers, calcium channel blockers, and adenosine [5,6]. Heart rate variability studies showed activation of sympathetic tone prior to the occurrence of these ventricular arrhythmias [7-9]. Sympathetic fibers of the ventromedial cardiac nerve (VMCN) and branches of ventrolateral cardiac nerve (VLCN) innervate the myocardium within the proximal pulmonary artery (PA) and the RVOT [10]. Recently, an animal model has been described for RVOT tachycardia by high-frequency stimulation (HFS) of the extravascular sympathetic nerves within the PA innervating the RVOT [11]. Similarly, HFS in the left pulmonary artery successfully induced RVOT-ventricular premature complexes (VPCs) and/or VT in a human model. However, in both models, the mechanism whereby a discrete area of myocardium in the RVOT becomes arrhythmogenic is yet to be clarified. Thus, the aim of this study was to investigate the neural mechanism of RVOT ventricular arrhythmias by using HFS within the PA in adult mongrel canine model

Methods: Twelve mongrel dogs (13.7 ± 1.3 Kg, 5 male dogs) were studied through midline thoracotomies. High-frequency stimulation (HFS) was applied to the proximal pulmonary artery (PA) to induce RVOT VT/VPC. An EnSite Array and a mapping catheter were used for electroanatomical mapping. The RVOT and PA were surgically excised for immunohistochemistry studies, including tyrosine hydroxylase (TH) stain for sympathetic nerves and choline acetyltransferase (ChAT) stain for parasympathetic nerves.

Conclusion: HFS of the proximal PA could induce RVOT VT/VPC. The sympathetic nerves were densely innervated to the origin of RVOT VT/VPC, indicating the critical role of sympathetic hyperactivity in the initiation and perpetuation of RVOT VT/VPC.
